CORS in ASP.NET Core

CORS specifies which origins, headers, and methods are permitted for cross-origin requests to the server.

```
builder.Services.AddCors(options =>
{
  options.AddPolicy(
    name: myCorsPolicy,
    policy =>
    {
      policy.WithOrigins("http://example.com",
        "https://www.elliotone.com")
        .AllowAnyHeader()
        .WithMethods("GET", "POST", "PUT", "DELETE");
    });
});
```

Applying CORS

CORS can be applied either globally or granularly.

Global Configuration

```
app.UseRouting();

app.UseCors(myCorsPolicy);

app.UseAuthorization();
```

Granular Control

VS

```
[EnableCors("MyCORSPolicy")]
[Route("api/[controller]")]
[ApiController]
public class ExampleController : ControllerBase
{

}
```

Elliot One

Applying CORS

CORS can also be applied using RequireCors(), which allows attaching a specific CORS policy directly to endpoints during routing configuration.

```
app.UseEndpoints((endpoints) => {
  endpoints.MapGet('/example', ExampleAction)
    .RequireCors(myCorsPolicy);

  endpoints.MapControllers()
    .RequireCors(myCorsPolicy);
});
```
